Abstract. The purpose of this study is to develop new effective air supply devices, taking into account the current level of development of science and technology and the emergence of modern high-tech materials. These include microperforated fabric ducts made of a polymer composite material. The holes in such ducts are cut with a laser. The results of studying the geometric characteristics of micro holes in a textile air duct section using an optical microscope are presented. It was found that the area of the holes varies in the range from 39629 μm^2 to 50955 μm^2 . The average value of the area of micro holes is $S = 47718 \mu\text{m}^2$, which corresponds to a diameter of $d = 242 \mu\text{m}$ (0.24 mm), and the diameter declared by the manufacturer is 0.2 mm. The results obtained make it possible to determine the resistance of a microperforated fabric air duct.

1 Introduction

Air quality is the most important indicator of the indoor working area microclimate which affecting productivity, well-being and individual comfort of a person [1-8]. Development of modern technologies is closely related with the use of new technologies and materials for air terminals production. One of the technologies is production of micro perforated textile terminals using polymer composite material – fabrics based on synthetic fibers. Modern laser technologies allow burning holes in textile material with a given pitch and diameter. The micro-holes diameter is 0.2-0.6 mm.

One of the advantages of the micro perforated textile terminal is possibility to supply air in the form of micro-jets with a small velocity directly into the human breathing zone [9]. Low air velocities in the breathing zone contribute to improving health of a person in the room and forming the required microclimate parameters and specified gas regime, taking into account variative external and internal factors [10-11].

Analysis of the works carried out by number of authors [12-15] leads to the conclusion that there are attempts to experimentally and theoretically study air distribution caused by textile air terminals, but the question remains unexplored concerning supply of air to the premises by means of textile terminals through micro holes.

2 Experimental

2.1 Materials and experimental procedure

The object of the study is an area of micro perforated textile terminal (Fig. 1) made of PMI fabric (100% polyester, continuous fiber). In order to study shape and size of micro-holes made with a laser in the fabric of a textile terminal, microscopic analysis was carried out, with participation of the Scientific and Educational Center "Nanomaterials and Nanotechnology" of Moscow University of civil engineering (MGSU), using SENTERRA dispersion Raman spectrometer combined with optical microscope (Fig. 2). Declared by the manufacturer diameter of micro-hole is 0.2 mm.

3. Results and discussion

Fig. 3 shows type of warp and weft threads interlacing of the polymer material used for textile terminals production.

Fig. 3. Type of interlacing of textile terminal threads.

Microscopic analysis of the micro-holes located in one row of the investigated area of the textile terminal made it possible to conclude that the holes boundary has irregular edges, but the shape is more inclined to round. The micro-hole area ($S, \mu\text{m}^2$) is not constant and varies in the range from $39629 \mu\text{m}^2$ to $50955 \mu\text{m}^2$, Table 1.

Table 1. Area of micro-holes

	Number of micro-holes									
	1	2	3	4	5	6	7	8	9	10
$S, \mu\text{m}^2$	48593	50955	48603	39629	41488	41700	45870	50238	43876	47718

Micro-holes №2 and №4 (Table 1) with maximum and minimum areas are shown in Fig.4.

Fig. 4. Appearance of the holes: a - hole №2 with maximum area, b - hole №4 with minimum area

Also, diameter of a single fiber thread was investigated using SENTERRA optical microscope. Results of microscopic analysis are given in Table 2. Average diameter of a single fiber is 16.5 μm (Fig. 4).

Table 2. Variation of the fiber thread diameter

	Number of micro-holes									
	1	2	3	4	5	6	7	8	9	10
Fiber thread diameter d, μm	16.8	17.1	17.1	16.7	16.5	16.1	16.7	16.1	15.7	16.0

4. Conclusion

The research carried out using optical microscopy method led to a conclusion that the micro-holes in the studied textile terminal are irregular and have rough edges. The hole area varies in the range from 50955 μm^2 to 39629 μm^2 . Average micro-hole area is $S=47718 \mu\text{m}^2$ that corresponds to a diameter of $d=242 \mu\text{m}$ (0.24 mm). Diameter of a single filament fiber varies from 16.0 μm to 17.1 μm . These results were obtained to use in further research of the micro perforated textile terminal resistance.
