Abstract. The existing technology for processing solid household waste (MSW) at waste transfer stations in the city of Tashkent does not allow obtaining high-quality raw materials for compost production. In this regard, a crushing and screening complex has been developed to produce compost with low energy and material consumption. The carried out theoretical and experimental studies made it possible to determine that the rotor blades should be installed along the rotor line with an angle equal to zero degrees. To overcome the resistance arising between the bottom of the crusher and the lower surface of the rotor, several holes with a diameter of 12 mm are drilled on the bottom of the crusher in the radial direction. It was found that the rotational speed of the electric motor of the crusher, as well as the sorting device, is 1500 min⁻¹, the angle of impact of organic waste on the rotor blades of the sorting device is approximately 45 degrees. The use of a crushing and screening complex made it possible to effectively grind and extract ballast inclusions from the composition of crushed organic waste by 85-90 percent.

1 Introduction

Population growth, rapid urbanization, rapid economic growth, and rising living standards in developing countries have significantly accelerated the rate of quantity and quality of solid waste generation [1]. Organic components, particularly food waste, refer to the number of biological wastes, according to [2, 11, 12] they make up about 25 to 40 percent of the total mass of the waste. According to calculations [4], the forecast of the annual volume of solid waste generation in the Republic of Uzbekistan is estimated at 14-14.5 million tons. Of these, approximately 4.5-5 million tons are organic waste, which in turn is a potential raw material for compost production.

But, one of the fundamental decisions is a separate type of waste collection and transportation system, to which most of the EU countries have switched [5, 6]. Separate waste collection has several indisputable advantages, so with a separate method of collection and transportation, the components are pre-sorted, which eliminates the need for preparatory waste sorting. In addition, with a separate method of collection and

transportation, the waste components retain their original form, which favourably affects the quality of raw materials.

With mixed collection and transportation, the components of the waste, mixing with organic (food) waste, become unusable, and thus the negative impact of waste on the environment increases. Unfortunately, at present it is quite difficult to organize separate waste collection everywhere, in our opinion, the reasons for this are:

weak advertising of the separate collection of solid waste in the media, in educational institutions, as well as among residents of apartment buildings; lack of motivation to encourage them to collect separately; inadequacy of technical means, namely, machines for collecting and transporting the solid waste, stations for reloading and landfills for waste disposal; insufficient environmental education among the population, etc.

Crushing and sorting of organic components of waste is relevant for several reasons: firstly, crushed and sorted waste from ballast inclusions can serve as raw material for the production of compost; secondly, due to the crushing of organic waste, the load on specialized vehicles intended for transporting waste to landfills will significantly decrease; thirdly, the emission of harmful substances into the atmosphere will be significantly reduced. In addition, it is important to note that by reducing the volume of waste disposal, the service life of landfills increases and saves land resources used for filling waste, which in turn affects the cost of waste disposal.

Such scientists as Hongmei Lu [7], A.M. were engaged in the study of the regularities of crushing and sorting of solid household waste, as well as methods of their selection. Gonopolsky [8], N. Marashlian [9], D. Bolzonella [10], Scott W Anderson [11], Steven P Hanson [12], Huaxun Ma, Lei Sun [13], TKXankelov [14], Sh.S. Tursunov [15], T. N. Lipatova [16], I. V. Lamzin, V.F. Zheltobryukhov, I.G. Shaikhyev [17], B.S. Kirin, A.N. Klokov [18], A.M. Musaev, R.G. Saiifulin [19], Mitsuhiro Oka [20], L.N. Reutovich, M.P. Arlievsky, N.A. Averyanova [21], V.F. Reshitko, G.Yu. Zatsepin, A. A. Shashin, G. Yu. Zatsepin [22], F.B. Teshome [23].

All existing methods of mechanical waste crushing are intended mainly for homogeneous and isotropic materials. But, the creation of efficient crushers, as well as sorting devices for low energy consumption and material consumption for crushing organic waste, causes significant difficulties since waste is a conglomerate of very diverse physical and mechanical properties containing fibrous inclusions (paper, wood, leather, etc.) and fragile components (bones, stones, etc.), as well as food waste.

Also, it is relevant to develop and create a crushing and screening complex designed for crushing and sorting waste similar in physical and mechanical properties, as crushers designed for crushing all waste components are very energy-intensive, and the output product is unusable due to the presence in it in primarily harmful impurities. Consequently, these crushing and screening complexes should be subject to very stringent requirements of energy, environmental and economic nature, which are as follows: low energy and material consumption indicators; minimum percentage of ballast inclusions; simplicity of design and reliability in operation.

### 2 Methods

To study the process of crushing organic components of solid household waste, a laboratory setup was made, consisting of a hopper, a working chamber, rotating knives, side and lower grates (Figure 1).
The hammer mill works as follows. The waste arriving for shredding falls into the loading hopper 1. Then the waste enters the working chamber 2, where it is accelerated to a rotation speed equal to the nominal rotation frequency of the electric motor 10 due to the creation of pressure using a hammer 4. The accelerating waste to the nominal rotation speed of the electric motor is crushed due to impact waste by knives 9 rigidly welded to the walls of the working chamber 2. In addition, the waste is crushed by colliding with the grate 5. The sharpened ends of the rotating rotors 5 contribute to the effective crushing of waste.

Fibrous and film waste is crushed by rubbing between the bottom of the rotor 5 and the bottom of the working chamber 2. By erasing, the waste passes through the grate 7 located on the bottom of the working chamber.

To study the effect of the shape and size of the crusher hammer (Figure 2) and the number of knives installed on the inner wall of the crusher working chamber on the crushing efficiency, a series of preliminary experiments were carried out. Fig. 2. shows rotor-fans with different blades.

![Diagram of the hammer mill](image-url)
For sorting ballast inclusions from the composition of crushed municipal solid waste, a device has been developed, and a patent for an invention has been obtained [24]. The device diagram is shown in Figure 3.

![Device Diagram](image)

**Fig. 3.** Device for sorting solid household waste.

Sorting of ballast inclusions from the rest of the mass of municipal solid waste is carried out as follows.

Ballast inclusions being transported along the conveyor belt fall into the bunker 7 of the throwing device, to prevent the formation of lumps in household waste, elastic rods 8 are installed in the receiving part of the bunker, in the amount of five pieces, on the top row there are three pieces. On the bottom row two pieces are the distance between the rods equal to 120 mm, then the loosened waste falls on the metal bar, to increase the gap between the wall and the bar, it is equipped with a compression spring.

Automatic adjustment of the gap between the metal plate and the hopper wall serves to eliminate possible clogging of the hole.

Further, the waste sliding along the base of the feed hopper in a uniform layer falls into the working area of the rotor 10 rotating at speed necessary to impart kinetic energy to its blades of heavy waste fractions. Heavier fractions fly off along a longer trajectory and fall into the distant bunker, less heavy fractions into the middle or near bunker, respectively.

### 3 Results and Discussion

To analyze the influence of operating factors on grinding and sorting waste and establish criterion dependencies, calculations were carried out based on the use of methods of the theory of similarity and dimensions using the π-theorem [25]. After making certain assumptions and restrictions, energy consumption for crushing organic components of solid

3 Results and Discussion

To analyze the influence of operating factors on grinding and sorting waste and establish criterion dependencies, calculations were carried out based on the use of methods of the theory of similarity and dimensions using the π-theorem [25]. After making certain assumptions and restrictions, energy consumption for crushing organic components of solid waste in hammer crushers on the design and technological parameters can be characterized by the following functional dependence.

\[ N = F(D, n, Q, L, S, \alpha) \]  

(1)

where \( N \) is the power of the crusher, Wt.; \( D \) is rotor diameter, mm; \( n \) is rotor speed, \( s^{-1} \); \( Q \) is the productivity of the crusher, kg/h; \( L \) is rotor length, mm; \( S \) is the surface area of the hammer, mm\(^2\); \( \alpha \) is hammer installation angle, degree. Using the method of zero dimensions with independent variables \( D, n, Q \), we obtain the following criterion equation

\[ \frac{N}{D^2n^2Q} = f \left( \frac{L}{D}, \frac{S}{D^2} \right) \]  

(2)

In order for the two crushers to comply with similar conditions, the respective criteria must be the same. In this case

\[ P_1 = \frac{N}{D^2n^2Q} = idem; \quad P_2 = \frac{L}{D} = idem; \quad P_3 = \frac{S}{D^2} = idem, \]  

(3)

Finding \( \Phi \) in the general case is difficult. You can search for individual partial dependencies, for example, to determine the relationship between the power of the crusher and the diameter of the rotor.

\[ \frac{N}{D^2n^2Q} = \Phi_1 \left( \frac{L}{D} \right) \]  

(4)

Assuming a proportional dependence in the first approximation, we have

\[ \frac{N}{D^2n^2Q} = k \frac{L}{D} \]  

(5)

where

\[ N = kDLQn^2 \]  

(6)

To determine the value of the coefficient \( k \), a series of staged experiments were carried out at the physical simulation bench of the crusher. From staged experiments, \( k = 7.5 \).

The final form of the dependence of the crusher power on the main design and technological parameters is

\[ N = 7.5DLQn^2 \]  

(7)

The process of sorting municipal solid waste is expressed by the following functional relationship

\[ d = F_1(R, n, g, \beta, \rho) \]  

(8)

where \( d \) is the length of the rebound of organic components of solid waste, mm; \( R \) is the radius of the rotor of the sorting device, mm; \( n \) is the frequency of rotation of the rotor of the sorting device, \( s^{-1} \); \( g \)-free fall acceleration, m/s\(^2\); \( \beta \) is the angle of rebound of waste constituents, degree; \( \rho \) is the density of MSW constituents, kg/m\(^3\).

Using the method of zero dimensions with independent variables \( R, n, \rho \), we obtain the following criterion equation

\[ \frac{d}{R} = f_1 \left( \frac{g}{Rn^2}, \beta \right) \]  

(9)
\[ P_1 = f_1(P_2^{-1}, P_3) \]  \hspace{1cm} (10)

where: \( P_1 = \frac{d}{R} \), \( P_2 = \frac{g}{Rn^2} \), \( P_3 = \beta \)

In order for two sorting devices to comply with similar conditions, the corresponding criteria must have the same values. In this case

\[ \frac{d}{R} = idem, \frac{g}{Rn^2} = idem, \beta = idem \]  \hspace{1cm} (11)

Let us construct the dependence on the plane \( P_1 = f_2(P_2^{-1}) \) with parameter \( P_3 \). Figure 4. presented dependence \( P_1 \) from \( P_2^{-1} \) with parameter \( P_3 \).

\[ \text{Fig. 4. Relationship between parameters in dimensionless coordinates.} \]

Based on the plotted graphs in dimensionless coordinates, it is possible to determine the boundaries of the region of optimal parameters, within which it is possible in a first approximation, to select the parameters of the sorting unit and explain some particular dependencies. High values \( \frac{d}{R} \) at the same values of the complex of quantities \( \left( \frac{g}{Rn^2} \right)^{-1} \) obtained due to an impact angle of approximately 45 degrees.

4 Conclusions

1. Due to minor changes, in particular, due to the drilling of holes on the bottom of the crusher, a hammer crusher design with low energy and material consumption was created.
2. The following main parameters of the crusher have been determined: \( n = 1500 \frac{ob}{min}; \alpha = 0^0; D = 270 \text{ mm}; L=100 \text{ mm}; S=2400 \text{ mm}^2 \).
3. The developed design of the sorting device allows to supply crushed organic waste to the rotor blade in a uniform layer, which significantly increases the efficiency of sorting.
4. The following main parameters of the crusher have been determined: \( n = 1500 \frac{ob}{min}; \beta = 45^0; R = 500 \text{ mm}; d = 2500 – 3000 \text{ mm}. \)
4. Conclusions
