Abstract. In this scientific article, we developed a model of block C that controls the position of the switches. A mathematical model of the block was calculated using a two-layer neural network along with the blocks of the block. An imitation model of the switch control block using the SoDeSys program is presented.

In the modeling process, it was studied that a multilayer neural network consists of one or more hidden layers of neurons-the entrance, exit, and the neurons located between them. And block C was determined that it was possible to model with the help of a 2-layer neural network and was expressed in the form of the following layers:

1-in the hidden layer: in the C block, the PK and MK relays are listed. This process indicated that the data coming from the PS or PST block would receive the PK and MK releases. At this layer, it is determined in which position the switches are located, and the data is transferred to the next layers.

2-in the hidden layer: the VZ relay in the C Block is indicated. Information coming from PK and MK relays shows the VZ relays acceptance process. In this layer, it is determined whether the switch is cut or not, and information is transferred to the next layers. In this layer, a certain position of the pushed conductor is determined

1 Introduction

At present, the reliable operation of automation and telemechanic relay devices and systems in railway transport ensures the safety of trains. However, after the speed of the rolling stock exceeds 160 km / h, relay devices and systems add additional time to ensure the safety of trains [1]. Ensuring the safety of trains at high speeds is currently achieved through the use of microprocessor-based devices and systems.

To ensure the safety of train traffic at the station, the devices of electrical interlocking systems must ensure the following following the rules of use of equipment [2, 3]:

- mutual locking of switches and traffic lights(closure);
- control of switch cutting with simultaneous closing of the traffic light bordering on this route;

*Corresponding author: sunnat_3112@list.ru

- control of switch sections, road occupancy, and switch condition on the control panel;
 - Possibility to route or separate traffic lights and traffic lights;
 - maneuvering actions on shunting stoplight indicators;
 - transfer the switches to local government, if necessary
- Following the rules of technical use of electrical interlocking devices are not allowed [2, 3]:
- opening the entrance traffic light when the route is busy;
 - moving the switch under the rolling stock;
 - opening traffic lights corresponding to this route if the switches are not placed in the appropriate position;
 - switching the switch entering the route or opening the traffic light of the opposite route.

At present, most of the relay electrical interlocking systems are block electrical interlocking systems. The block electrical interlocking system consists of the dial and executive groups. Executive group schemes control the locking (closing) of routes and the opening of traffic lights and the cancellation of routes, automatic and artificial separation. The Executive Group has the following blocks VI, VII, VIII, VD, Vx, VxD, MI, MII, MIII, P, UP, SP, PS, PST, and C [2-18].

2 Methods

Of these, block C is designed to check the suitability of the switch position on the route being installed and to disconnect the route installation chain. Block C is set separately for each switch conductor in binary switches and single switches. Block C consists of PK relays that control the plus position of the switch, MK, which controls the minus position, and VZ, which controls the cross-section of the switch (Figure 2.).

Fig. 1. Block C is connected to the route setup and disconnection chain.

Block C connects the route setup and disconnection chain depending on the position of the switch. (Figure 1a, b). If the switch is in the plus position, block S to set the route and disconnect the chain "11 – 21", "12 – 22", "13 – 23", "14 – 24", "15 – 25", "16 – 26", "17 – 27", "18 – 28" (Figure 1a) through the chain, if in the minus position "11 – 111", "12 –

112", "13 – 113", "14 – 114", "15 – 115", "16 – 116", "17 – 117", "18 – 118" (Figure 1b), connects through the chain, if the switch loses control, the chain is disconnected via the contact of the VZ relay in the block. When other inputs and outputs of block C are not used in the route setup and disconnection chain, they use the relay PK, MK, VZ, if necessary, receive a repeater PK, MK, VZ relay and display the status of the switch.

The position of the relays of block C was calculated using discrete mathematics. This article presents a mathematical calculation of the block using its neural set to accurately control its state.

A multilayer neural network consists of a neural network consisting of one or more latent layers of neurons entering, exiting, and located between them. In addition to the input and output layers, these neural networks also include intermediate, latent layers. Such networks have much greater potential than single-layer neural networks, but methods for preparing latent layer neurons have been developed relatively recently.

Fig.2. Appearance of the block controlling the position of the switch.

Fig.3. Control the status of the switch using a two-layer neural network.

3 Results and Discussion

The work of the latent layers of neurons can be compared to the work of a large factory. The factory product (output signal) is assembled step by step on the machines. Some intermediate result is obtained after each machine. Hidden layers also convert input signals into some intermediate outputs.

In Figure 1, we consider the operation of block C, taking into account the inputs and outputs according to the model of an artificial neuron set [19-25]. In doing so, we build a set of neurons in two layers. Its layers are listed in Table 1.

In this case, the equations on the chains of switch conductors are constructed. The article presents the equation of the chain "11 - 21".

In the input layer: The data of the cases of pullus (1) or minus (2) of the switch coming from the PS or PST blocks are given in the form X_1 and X_2 . This layer stores data from the PS or PST blocks and transmits the data to the C block.

In the 1st hidden layer: relays PK (3) and MK (4) in block C are included. It is shown that the data coming from the PS or PST block is received by the relays PK (f_3) and MK (f_4). In this layer, the position of the switch is determined, and the data is transmitted to the next layers.

$$f_3 = x_1 w_1, y_3(f_3) = y_3(x_1 w_1) \quad (1)$$

$$f_4 = x_2 w_2, y_4(f_4) = y_4(x_2 w_2) \quad (2)$$

In hidden layer 2: VZ relay in block C is shown. It shows the process of receiving data from the relay PK and MK VZ relay. In this layer, it is determined whether the switch is cut or not, and information is passed to the next layers. In this layer, the exact position of the switch conductor is determined (Figure 4, a,b,c,d).

$$f_5 = y_3 w_{32} + y_4 w_{41}, y_5(f_5) = y_5(y_3 w_{32} + y_4 w_{41}) \quad (3)$$

In the output layer: in the C block "11 - 21", "12 - 22", "13 - 23", "14 - 24", "15 - 25", "16 - 26", "17 - 27", "18 - 28", "11 - 111", "12 - 112", "13 - 113", "14 - 114", "15 - 115", "16 - 116", "17 - 117", "18 - 118", the indication chains are "turn on the green, yellow and red lights" and the "most commonly checked circuit" chains are shown. In this layer: the reception of data from the previous hidden layers and the indication chains in the plus or minus position of the switch is carried out by the activation of the chains "turn on the green, yellow and red lights" and "check the circuit".

$$f_6 = y_3 w_{31} + y_5 w_{51}, y_6(f_6) = y_6(y_3 w_{31} + y_5 w_{51}) \quad (4)$$

Table 1. Propagation of a two-layer neural network of the switch block.

Layers	№	Functions	Contents
Input	1.		PC access
	2.		Access to MK
Hidden layers	3.		PC control
	4.		MK control
	5.		Access to VZ
Output	6.		"11 – 21" chains
	7.		"12 – 22" chains
	8.		"13 – 23" chains
	9.		"14 – 24" chains
	10.		"15 – 25" chains
	11.		"16 – 26" chains
	12.		"17 – 27" chains
	13.		"18 – 28" chains
	14.		"11 – 111" chains
	15.		"12 – 112" chains
	16.		"13 – 113" chains
	17.		"14 – 114" chains
	18.		"15 – 115" chains
	19.		"16 – 116" chains
	20.		"17 – 117" chains
	21.		"18 – 118" chains
	22.		"Start Z" indication chain
	23.		"Start K" indication chain
	24.		"Start J" indication chain
	25.		From PC to compatibility checker circuit
	26.		From MK to the conformity checker circuit

Fig.4. Simulation of the switch status using CoDeSys program: a-switch in the minus position, b-switch in the plus position, s-switch in the faulty state (all functions of the hidden layer determining the status of PK, MK and VZ relays are active), d-switch in the faulty state (PK, MK and all functions of the latent layer determining the status of the VZ relays are inactive)

4 Conclusions

In conclusion, it can be said that the unit that controls the status of the switches, after determining the exact position of the switch, activates the relay indicating the status of the switch and activates the indicator lights corresponding to the indication chains. In this scientific paper, a model of switch status detection using a two-layer neural network and an imitation model using SoDeSys software were created. This allows the electrical interlocking systems to intelligently determine the data when determining the position of the module or block that controls the position of the switches.
