Abstract. Swamp eel (Monopterus albus) processing produced by-products such as heads that possess a high protein, carbohydrate, lipid, and energy content. Swamp eel heads were hydrolyzed (SEHPH) and tested for their antibacterial activity against histamine-producing bacteria (HPB) to explore the potency. The hydrolysis was conducted by a commercial papain enzyme PAYA (concentration 4%) with various hydrolysis times (0, 60, 120, and 180 minutes) at 60°C with pH 5. The results indicated that increasing hydrolysis time increased solubility and the degree of hydrolysis. The inhibitor concentration 50 test using microdilution of SEHPH inhibited 50% against three HPB named *Citrobacter* sp. (CK1), *Klebsiella* sp. (CK13), and *Morganella morganii* (TK7) at 20 mg/ml. The optimum antibacterial activity test by disk diffusion method was formed by each minute of hydrolysis with the best inhibition zone to *Klebsiella* sp. (CK13). The macrodilution method showed the highest inhibition was produced by 180 hydrolyses with 45% on CK1, 54% on CK13, and 48% on TK7. These results indicated that SEHPH has potency as an antibacterial agent to reduce histamine-producing bacteria.

1 Introduction

Histamine (C₅H₉N₃) is a biogenic amine causing food poisoning. Histamine is formed by the decarboxylation process of the histidine amino acid by histamine-producing bacteria (HPB). These bacteria generally live in seawater and naturally reside in the gills and digestive tract of fish. According to European Union Data, consumption of uncooked fish and fishery products is the leading cause of histamine poisoning. The histamine formation can be very fast, which is about 2–3 hours at 20°C. Histamine is usually found in food products, scombroid fish including tuna, mackerel, anchovy, sardines, bonito, marlin, herring, and mahi-mahi fish [1,5], fermented fish products including traditionally processed such as salted fish, *pindang*, and *peda* [2], wine, cheese, and meat products [3]. The cooking process in scombroid fish only removed HPB but could not release histamine that had formed [4]. In the case of fermented processed products, research showed that fermented food tends to have

* Corresponding author : primaputra@ugm.ac.id
a higher histamine content than the fish itself [5]. HPB can quickly form if fish are not handled properly, causing disease for those who consume them. One way to prevent the formation of HPB is to use antibacterial compounds that can be obtained from fish protein hydrolysate (FPH).

Protein hydrolysate is a product of polypeptides, dipeptides, and amino acids, which can be produced from materials through protein hydrolysis. FPH can be hydrolyzed efficiently by using enzymatic hydrolysis because it makes high non-complex protein content. Papain is one of the proteolytic enzymes produced from papaya fruit latex or its leaves. It also has a commercial papain enzyme named “PAYA”. Various types of peptides contained in the fish protein hydrolysate had some functions such as an anti-hypertensive [4], as an anti-coagulant [5], as an anti-oxidant [4], as an anti-diabetic [6], as an anti-cancer [7], and as an antibacterial. Antibacterial is used explicitly for groups of harmful bacteria. The antibacterial mechanism damages cell walls, changing the membrane permeability, disrupting protein synthesis, and finally inhibiting an enzyme. Even though many studies found the relation of antibacterial activity in several types of fish protein hydrolysate, the study of swamp eel protein hydrolysate against HPB was rarely seen. Since there were many swamp eel farming in Indonesia, it is necessary to explore the antibacterial activity of swamp eel head protein hydrolysate. The hydrolysis was done with 4% papain according to [11] on various hydrolysis times with commercial papain enzyme “PAYA” at optimum pH 5 and temperature 60°C.

2 Materials and methods

2.1 Material

The primary material was a swamp eel head obtained from small-scale industries Citra Rasa, Godean, Yogyakarta. The charges were washed, placed in a plastic bag, and then stored in the refrigerator at -10°C until further use. This study was conducted at Fishery Product Quality and Safety Laboratory, Universitas Gadjah Mada, Yogyakarta. The commercial papain enzyme “PAYA” with the activity of 1.053 U/g [12]. Three HPB was used for the determination of antibacterial activity: *Morganella morganii* (TK7), *Citrobacter* sp. (CK1), and *Klebsiella* sp. (CK13). Tryptic Soy Broth (TSB) and Tryptic Soy Agar (TSA) were used for cultured bacteria.

2.2 Hydrolysis of swamp eel head protein hydrolysate (SEPH)

This method was determined by using the method with slight modification [11]. Swamp eel head is first boiled to remove its natural enzyme. For each batch, minced swamp eel heads were mixed with aqua dest with a ratio of 1: 2 (w/v). The mixture was blended with a papain enzyme of 4% concentration at pH 5. The hydrolysis using water bath shaker with the temperature at 60°C for 0 minutes, 60 minutes, 120 minutes, and 180 minutes as treatments (SEPH0, SEPH60, SEPH120, and SEPH180). Then, the hydrolysis process was terminated by heating the sample 80°C for 10 mins to inactivate the papain activity. Swamp eel head protein hydrolysate was centrifuged for 20 mins at 4°C and 3500 rpm, filtered and freeze-dried. The SEPH was stored at -20°C for the subsequent analysis.

2.3 Water soluble protein content of SEPH

This assay used Coomassie brilliant blue G-250 at 595 nm to count the protein solubility and polypeptides within amino acids [13]. To construct a standard curve, this study used Bovine...
temperature at 60°C for 0 minutes, 60 minutes, 120 minutes, and 180 minutes as treatments. The hydrolysis using water bath shaker with the enzyme of 4% concentration at pH 5. The hydrolysis was done with 4% papain according to [11] on various hydrolysis times with commercial papain enzyme “PAYA” at optimum pH 5 and temperature 60°C. Then, the hydrolysis process was terminated by heating the sample 80°C for 10 mins to inactivate the papain activity. Swamp eel heads were mixed with aqua dest with a ratio of 1:2 (w/v). The mixture was blended with a papain head is first boiled to remove its natural enzyme. For each batch, minced swamp eel heads were processed properly, causing disease for those who consume them. One way to prevent this is to explore the antibacterial activity of swamp eel head protein hydrolysate against HPB was rarely seen. Since there were many swamp eel farming in Indonesia, it is necessary to explore the antibacterial activity of swamp eel protein hydrolysate. 

### 2.1 Material

Protein hydrolysate is a product of polypeptides, dipeptides, and amino acids, which can be produced from materials through protein hydrolysis. FPH can be hydrolyzed efficiently from materials through protein hydrolysis. FPH can be hydrolyzed efficiently by using enzymatic hydrolysis because it makes high non-complex protein content. Papain can be produced from materials through protein hydrolysis. FPH can be hydrolyzed efficiently by using enzymatic hydrolysis because it makes high non-complex protein content. Papain is a proteolytic enzyme that can be used to hydrolyze fish protein to form HPB. Antibacterial activity is used explicitly for groups of harmful bacteria. The antibacterial mechanism of SEHPH is to use antibacterial compounds that can be obtained from fish protein hydrolysate. The hydrolysate. The hydrolysis was done with 4% papain according to [11] on various hydrolysis times with commercial papain enzyme “PAYA”. Various types of peptides contained in the fish protein hydrolysate had some functions such as an anti-hypertensive [4], as an anti-coagulant [5], and as anti-inflammatory [6].

### 2.2 Methods

#### 2.2.1 Freeze-drying

Freeze-drying was used to prepare the SEHPH for further analysis. The SEHPH was stored at -20°C for the subsequent analysis. The SEHPH was stored at -20°C for the subsequent analysis.

#### 2.2.2 Hydrolysate preparation

For each batch, minced swamp eel heads were placed in a plastic bag, and then stored in the refrigerator at -10°C until further use. This study was conducted at the Fisheries Product Quality and Safety Laboratory, Universitas Gadjah Mada, Yogyakarta. The commercial papain enzyme named “PAYA” was used to hydrolyze the swamp eel heads. The hydrolysis was done with 4% papain according to [11] on various hydrolysis times with commercial papain enzyme “PAYA”. Various types of peptides contained in the fish protein hydrolysate had some functions such as an anti-hypertensive [4], as an anti-coagulant [5], and as anti-inflammatory [6].

#### 2.2.3 Hydrolysate preparation

The hydrolysate was prepared by blending the minced swamp eel heads with aqua dest with a ratio of 1:2 (w/v). The mixture was blended with a papain head is first boiled to remove its natural enzyme. For each batch, minced swamp eel heads were processed properly, causing disease for those who consume them. One way to prevent this is to explore the antibacterial activity of swamp eel head protein hydrolysate against HPB was rarely seen. Since there were many swamp eel farming in Indonesia, it is necessary to explore the antibacterial activity of swamp eel protein hydrolysate. The hydrolysate. The hydrolysis was done with 4% papain according to [11] on various hydrolysis times with commercial papain enzyme “PAYA”. Various types of peptides contained in the fish protein hydrolysate had some functions such as an anti-hypertensive [4], as an anti-coagulant [5], and as anti-inflammatory [6].

#### 2.2.4 Degree of hydrolysis

The method was determined by using the method with slight modification [11]. Swamp eel heads were boiled to remove its natural enzyme. For each batch, minced swamp eel heads were mixed with aqua dest with a ratio of 1:2 (w/v). The mixture was blended with a papain head is first boiled to remove its natural enzyme. For each batch, minced swamp eel heads were processed properly, causing disease for those who consume them. One way to prevent this is to explore the antibacterial activity of swamp eel head protein hydrolysate against HPB was rarely seen. Since there were many swamp eel farming in Indonesia, it is necessary to explore the antibacterial activity of swamp eel protein hydrolysate. The hydrolysate. The hydrolysis was done with 4% papain according to [11] on various hydrolysis times with commercial papain enzyme “PAYA”.

#### 2.2.5 Antibacterial activity

The antibacterial activity was measured through the formula below:

\[
\text{% inhibition} = \frac{\text{OD of negative control} - \text{OD of sample}}{\text{OD of negative control}} \times 100\% 
\]  

The method was determined by using the method with slight modification [11]. Swamp eel heads were boiled to remove its natural enzyme. For each batch, minced swamp eel heads were mixed with aqua dest with a ratio of 1:2 (w/v). The mixture was blended with a papain head is first boiled to remove its natural enzyme. For each batch, minced swamp eel heads were processed properly, causing disease for those who consume them. One way to prevent this is to explore the antibacterial activity of swamp eel head protein hydrolysate against HPB was rarely seen. Since there were many swamp eel farming in Indonesia, it is necessary to explore the antibacterial activity of swamp eel protein hydrolysate. The hydrolysate. The hydrolysis was done with 4% papain according to [11] on various hydrolysis times with commercial papain enzyme “PAYA”.

#### 2.2.6 Statistical analysis

The sample was conducted in triplicate, then represented as mean ± standard deviation for each analysis. Post-hoc test (Tukey analysis) to discover the difference between treatments was used after determining the analysis variance (ANOVA) as comparative statistical analysis (p<0.05) using SPSS software.

### 2.4 Degree of hydrolysis

The Bradford method was used to determine the percentage of solubilized protein in 10% trichloroacetic acid (TCA), and the Kjeldahl method for calculating the total protein content [14]. 500 µl of protein hydrolysate were blended with 500 µl of 20% of TCA. The mixture was incubated at 30 minutes and, after that, was centrifuged at 3000 rpm. The supernatant was added by 500 µl Bradford reagent and mixed gently by vortexing. The sample’s absorbance was 595 nm and followed the BSA curve standard. The degree of hydrolysis (DH) was estimated by:

\[
\text{DH (%) = \frac{\text{soluble protein in 10% TCA}}{\text{total protein content}}} \times 100\%
\]  

### 2.5 Antibacterial activity

The antibacterial activity determined by using macrodilution method [15] and disk diffusion method [16] with HPB used were Morganella morganii (TK7), Citrobacter sp. (CK1), and Klebsiella sp. (CK13). The inhibition concentration 50 (IC50) was performed with various concentration which are 1.25, 2.5, 5, 10, and 20 mg/ml [17]. HPB (each Morganella morganii (TK7), Citrobacter sp. (CK1), and Klebsiella sp. (CK13)) suspension with OD 0.1 was added 20 µl with kanamycin positive control. Tubes were vortexed and incubated for 24 hours at 37°C. After incubation, the OD of each concentration has measured the absorbance at 600 nm. The IC50 concentration was then used in the antibacterial activity assay. The antibacterial activity was measured through the formula below:

\[
\text{% inhibition} = \frac{\text{OD of negative control} - \text{OD of sample}}{\text{OD of negative control}} \times 100\% 
\]  

The macrodilution method was done according to [15] as follows: a 5 ml TSB was prepared in a test tube, and 1% (OD 0.1) of each HPB was added into the tube. The specific concentration of sterile SEHPH was then added into the tube, followed by incubation for 24 hours at 37°C. After incubation, the OD of each test tube was measured at 600 nm. The percent inhibition was measured as mentioned above.

Disk diffusion method was done according to [16]. The 50 µl of each HPB OD 0.1 was spread into TSA with drigalski. 6 mm sterile paper disk which previously added 20 µl of each treatment (negative control, positive control, SEHPH0, SEHPH60, SEHPH120, and SEHPH180) were placed on the agar. TSA plates were incubated for 24 hours at 37°C. After 24 hours, the clear zone around the disk has measured the width of the antimicrobial inhibition zone according to the equation below:

\[
\text{% antibacterial activity} = \frac{\text{diameter of inhibition zone}}{\text{disk diameter}} \times 100\%
\]  

### 2.6 Statistical analysis

The sample was conducted in triplicate, then represented as mean ± standard deviation for each analysis. Post-hoc test (Tukey analysis) to discover the difference between treatments was used after determining the analysis variance (ANOVA) as comparative statistical analysis (p<0.05) using SPSS software.
3 Results

The swamp eel (Monopterus albus) head is a by-product of swamp eel's small-scale industries in Yogyakarta as a non-edible portion. The head takes about 11.71% of total weight of the swamp eel. The head has the highest ash content, protein content, and carbohydrate (1.86 %, 16.32%, and 3.57%, respectively). However, meat has significantly higher amounts of energy (233.05 kal/100g, respectively). Proximate analyses of the swamp eel are shown in Table 1.

3.1 Water soluble protein content of SEHPH

The optimum protein solubility is produced at a hydrolysis time of 120 minutes (SEHPH120) with 120 ± 2.27 ppm when the lower protein solubility hydrolysis time of 0 minutes was only 74.45 ± 2.5 ppm. As described in Figure 1, the protein solubility of SEHPH increased with increasing the hydrolysis time from 74.45 ± 2.5 ppm at 0 minutes to 120.37 ± 1.03 ppm at 180 minutes.

![Fig. 1. Water soluble protein content of swamp eel protein hydrolysate (SEHPH) at a different time of hydrolysis (different alphabet at column mean there has significance at each other).](https://example.com/fig1)

3.2 Degree of hydrolysis

In this research, 120 minutes of SEPH (SEHPH120) hydrolysis gave the optimum values at 12.09 ± 0.282%. The results show that DH increased with increasing hydrolysis time from 7.82% ± 0.14 at 0 minutes to 12.54 ± 0.37 at 180 minutes. 120 minutes of hydrolysis doesn’t have a significant difference from 180 minutes of hydrolysis. DH and protein solubility figures indicate that enzymatic hydrolysis will stop to a specific time of hydrolysis because enzymes have run out of protein bonds.

### 3.3 Antibacterial activity

The IC₅₀ assay concluded that concentration 20 mg/ml showed 50% inhibition against *Morganella morganii* (TK7), *Citrobacter* sp. (CK1), and *Klebsiella* sp. (CK13). The 20 mg/ml concentration was then used for every antibacterial activity. The results are shown in Figure 3. the SEHPH 0 minutes (SEHPH0) hydrolysis has a significant difference with other hydrolysis time with the macrodilution method. The macrodilution method showed the highest inhibition was produced by 180 hydrolyses with 45% on CK1, 54% on CK13, and 48% on TK7.

4 Discussion

4.1 Hydrolysis of swamp eel head protein hydrolysate (SEPH)

The yield of swamp eel head protein hydrolysate (SEPH) was accounted for about 2.83% of the total weight of the head sample used. Moreover, the result of hydrolysate also depends on the quality of samples and types of the enzyme were used. The SEPH yield was lower than eel protein hydrolysate (EPH) at 6.97% [18] and the yield of freshwater carp (*Catla catla*) hydrolysate at 6.60% [19]. It can be caused by SEPH having a different substrate ratio during hydrolysis compared to EPH and freshwater carp (*Catla catla*) hydrolysate. In the enzymatic process, the yield depends on the type of enzyme and substrate, hydrolysis conditions (pH, temperature, time, enzyme/substrate ratio), solvent ratio, and stirring speeds [20].

4.2 Water-soluble protein content of SEPH

Fig.1. shows the protein solubility (ppm) of SEPH obtained from commercial papain with various times of hydrolysis. Protein solubility is highly affected by protein concentration because when protein concentration increases, there is more chance for protein molecules to get closer to each other [21]. It will promote protein-protein interactions and make solubility decrease. Figure 1. proved that hydrolysis time had a significant effect on protein solubility. The protein solubility from tuna eye protein hydrolysate has 94.90 ± 0.002 % (p<0.05) after 6-hour hydrolysis with papain enzyme (Merck) [22]. In another study, fish frame processing waste has 97.35% soluble protein by 60 minutes time of hydrolysis using papain enzyme (*Carica papaya* latex) [23].

4.3 Degree of hydrolysis

The degree of hydrolysis (DH) is usually used to determine the percentage of peptide bonds cleaved and describe the properties of protein hydrolysate. Figure 2 shows the increases of DH with increasing hydrolysis time. The higher value of DH, the more efficient the hydrolysis process, and the proteins were cleavage. But DH can depend on many factors, such as types of enzyme used for hydrolysis, PAYA, as a commercial enzyme, has low purity levels of papain, and it is a combination of the enzyme papain, salt, and sugar that is used for meat tenderizer products. Because of that, hydrolysates were hydrolysis with commercial enzyme has lower DH value than pure enzyme. Compared to other studies FPH, DH from SEPH was still lower. The protein hydrolysate from *Clarias batrachus* has 53.48% after 180 minutes hydrolysis with papain enzyme (Rockford, IL, USA) [24] and protein
because when protein concentration increases, there is more chance for protein molecules to various times of hydrolysis. Protein solubility is highly affected by protein concentration Fig. 1. shows the protein solubility (ppm) of SEHPH obtained from commercial papain with 4.2 Water-soluble protein content of SEHPH [20].

4.1 Hydrolysis of swamp eel head protein hydrolysate (SEHPH)

The degree of hydrolysis (DH) is usually used to determine the percentage of peptide bonds of the total weight of the head sample used. Moreover, the result of hydrolysate also depends on the quality of samples and types of the enzyme were used. The SEHPH yield was lower of the total weight of the head sample used. Nevertheless, more research is needed to determine the amino acid composition in the Swamp eel head to prove its influence on antibacterial activity. The addition of a hydrolysis time of more than 180 minutes is also suggested.

120 minutes of swamp eel head hydrolysis has more optimum protein solubility and degree of hydrolysis, 120 ± 2.27 ppm, and 12.09 ± 0.282%. SEHPH also has antibacterial activity against HPB, with MIC reaching IC50 at 20mg/ml concentration in SEHPH 180 minutes hydrolysis. SEHPH with 0 minutes hydrolysis time is significantly different from SEHPH 60 minutes hydrolysis, 120 minutes hydrolysis, and 180 minutes hydrolysis against HPB. Peptides from SEHPH have antibacterial activity and much increased after hydrolysis. Hydrophobic amino acids were formed during hydrolysis would initiate peptide interaction with the surface of the bacteria then damage the bacteria membrane, membrane physiological disturbances such as cell biosynthesis, cell division, or translocation across the membrane to interact with the cytoplasm [26]. Antibacterial activity from A. lecanora protein hydrolysate effectively inhibited growth S. aureus and E. coli hydrolyzed with papain enzyme, and also can effectively inhibit Pseudomonas sp. and P. aeruginosa hydrolyzed with bromelain enzyme [27]. Other research reported that half-fin anchovy protein hydrolysate (HAHp) also could inhibit Gram-negative (E. coli, P. fluorescens, Proteus vulgaris, and P. aeruginosa) and Gram-positive (S. aureus, Bacillus megaterium, and Sarcina lutea) because it reached 47. 71% hydrophobic amino acid as antibacterial peptides [28]. Antibacterial activity of peptides can be influenced by hydrophobicity and combination specific amino acids like histidine, arginine, alanine, valine, and leucine [29]

4.4 Antibacterial activity

Peptides from SEHPH have antibacterial activity and much increased after hydrolysis. Hydrophobic amino acids were formed during hydrolysis would initiate peptide interaction with the surface of the bacteria then damage the bacteria membrane, membrane physiological disturbances such as cell biosynthesis, cell division, or translocation across the membrane to interact with the cytoplasm [26]. Antibacterial activity from A. lecanora protein hydrolysate effectively inhibited growth S. aureus and E. coli hydrolyzed with papain enzyme, and also can effectively inhibit Pseudomonas sp. and P. aeruginosa hydrolyzed with bromelain enzyme [27]. Other research reported that half-fin anchovy protein hydrolysate (HAHp) also could inhibit Gram-negative (E. coli, P. fluorescens, Proteus vulgaris, and P. aeruginosa) and Gram-positive (S. aureus, Bacillus megaterium, and Sarcina lutea) because it reached 47. 71% hydrophobic amino acid as antibacterial peptides [28]. Antibacterial activity of peptides can be influenced by hydrophobicity and combination specific amino acids like histidine, arginine, alanine, valine, and leucine [29]

4 Conclusion

This research was supported by research grant RTA Universitas Gadjah Mada No. 3143/UN.1.P.III/DIT-LIT/PT/2021.
