Mechanical Properties of FSW Joints in Magnesium Alloy at Different Rotational Speeds

P. Vijayaraghavan, Yashwant Singh Bisht, Muntather Almusawi, Subramani K, Deepti Sharma

Abstract: Magnesium (Mg) has become a focus in the transportation industry due to its potential in reducing fuel consumption and gas emissions while improving recyclability. Mg alloys are also known for their low neutron absorption, good resistance to carbon dioxide, and thermal conductivity, which makes them suitable for use in industrial equipment for nuclear energy. There has been an increasing interest in the research and development of Mg alloys. These are the lightest of all metallic structural materials and are approximately 33% lighter than aluminum (Al) and 75% lighter than ferrous (Fe) alloys and have excellent specific mechanical properties. In this work, FSW of AZ31B Alloy was examined at various rotational speeds of 900 – 1440 rpm, with a fixed welding speed of 40 mm/min and a 2° tool tilt angle using an HSS tool. The mechanical properties were compared for different rotational speeds. The quality of FSW joints is dependent on the input value of heat and material flow rate, which are influenced by the process parameters. Higher rotation speeds may cause abnormal stirring, resulting in a tunnel defect at the weld nugget due to increased strain rate and turbulence.

1. Introduction

Friction stir welding is a revolutionary manufacturing method that presents many benefits compared to traditional welding methods [1,2]. These benefits include better mechanical properties, ease of processing, and the ability to achieve welds with minimal distortion.

properties, low residual stresses, and defects [3]. The tool rotation and translation together which leads to material movement from forward facing to the back pin, which can be quite complex due to various geometrical features of the tool [4]. The tool applies substantial forging force to consolidate the plasticized metal behind it [5]. Insufficient axial pressure during the welding process can cause flash formation when the material escapes from the weld cavity [6]. Different types of joints can be done on FSW such as butt [7], lap [8], T-butt [9] and fillet joints etc [10].

K. Kumar et al [11] studied two distinct modes of material flow in friction stir welding are referred to as pin and shoulder flow. The geometric of pin-driven flow which combined with the vertical measure of material due to shoulder interaction, results in the formation of onion rings. Ugendera et al. [12] concluded that rotational speed of 1120 rpm formed superior mechanical properties compared with other speeds. To establish optimal parameters for friction stir welding AZ31B magnesium alloy. The five different tool pin profiles with 3 different tool shoulder sizes to produce the joints.

Dhanesh G. et.al [14] explained the tool profile and orientation heat on the material during welding at various speeds. Malarvizhi et al [15] focused tool shoulder diameter, which is a key source of heat generation during the welding process of dissimilar AA6061 and AZ31-Mg. the shoulder diameter of 21 mm which had been almost 4 times the thickness of sheet. B.Mansoor et al [16] analysed tool rotation speed/welding speed between Al and Mg alloys. The intermetallic phases that formed in the stirred zone and evaluated their influence on the microhardness and overall mechanical properties of the weld. The welding process can cause liquation, resulting in the formation of intermetallics at the joint interface [17]. Kulwant Singh et.al [18] provides a general overview of the basic principle of friction stir welding, along with a description of various aspects related to the welding of magnesium alloys.

In this work, we analysed the FSW welding joint for AZ31B Alloy at Different Rotation Speeds along with mechanical testing.

2. Materials and methodology

AZ31B is a type of magnesium alloy known for its excellent strength and ductility at room temperature. It also boasts impressive corrosion resistance and weldability, making it a popular choice in various applications. For instance, AZ31B is commonly used in the production of airplane fuselages, laptop and cell phone cases, speaker cones, and concrete tools. Moreover, the alloy can be subjected to super forming techniques at high temperatures [19-23]. For this study, we have selected AZ31B as our base metal. This type of metal belongs to the family of wrought magnesium alloys and has a general chemical composition that is presented in Table 1.

We examined rolled plates made of MgAZ31B alloy, with a thickness of 6mm. A square butt joint measuring 150mm x 60mm x 6mm was fabricated for the investigation. This joint was produced using the FSW welding technique. The setup of the machine for FSW process as shown in Fig.1.
3. Materials testing

Tensile strength

To prepare the specimens for tensile testing, we cut the welded joints using milling cutters and machined them to the required dimensions [24-27]. The transverse tensile testing specimens were then fabricated following the ASTM E8/E8M11 standards, as shown in Fig. 2 [28, 29].

Micro hardness

We determined the hardness of the welded joint by measuring it with a Vickers hardness machine using a load of 100g at 20 seconds time [30, 31]. The micro hardness was evaluated based on the cross-section of the welded joint and the stir zone.
4. Result & discussion

Tensile properties

We evaluated several tensile properties of the fabricated welding, including tensile strength, micro hardness, density, % of elongation, and heat input. We prepared the tensile specimens according to the ASTM E8/E8M11 standards and conducted the tensile testing using a digital tensometer with a load capacity of 60KN.

The result of the tensile test is shown in Table 2.

The micro hardness of fabricated welded joint done at stir zone of welded joint, the micro hardness of metal is tested on the Vickers hardness tester and result of the hardness of welded as shown in the Table 2.

We conducted the hardness test with a load of 100 grams and calculated the heat input.

It is perceived that the welded joint with a rotational speed of 1120 rpm and a welding speed of 40mm/min had high tensile strength and a better percentage of elongation. This joint also had moderate heat input and hardness. As a result, we conclude that the welded joint with a rotational speed of 1120 rpm is preferred for achieving high tensile properties.

The highest elongation (11.43%) is observed at 1440 rpm in Fig. 3.

We also measured the density of the stir zone in the welded joint. The density of the base metal was determined to be 1.77g/cm³. We found that the welded joint with a rotational speed of 900 rpm had a higher density of 1.87g/cm³ which shown in Fig. 5.

The hardness value also increased at 1440 rpm which possess 96.53Hv illustrated in Fig. 6.

5. Conclusion

- Lower rotational speed leads to a higher stirred zone microhardness than the base material, and there is an optimal combination of tool material and rotational speed to achieve high strength properties in the stir zone.
The ultimate tensile strength of the fabricated joint at a rotational speed of 1120 rpm is higher than those at 900 and 1140 rpm. The fabricated joint at a rotational speed of 1440 rpm shows higher hardness compared to other joints at 900 and 1120 rpm. The density of the stir zone of the 900 rpm joint is lower than that of the other joints. The joint fabricated at 1120 rpm with a welding speed of 40 mm/min exhibits superior tensile strength and moderate hardness and % elongation, making it the most feasible option for FSW of the metal.
