Study on prediction and influencing factors of energy consumption in Jiangxi province

Hui Xia

School of Information Engineering, Jingdezhen University, Jingdezhen, 333000, China

Abstract: This study aims to determine the main factors affecting energy consumption in Jiangxi Province, and to forecast energy consumption effectively. An indicator system of energy consumption was constructed based on the relevant data from 1996 to 2021, which was used to analyze the relationship between energy consumption and energy consumption structure, industrial structure and energy price. Based on the statistical data from 1996 to 2021, comprehensive analysis and regression analysis were conducted to determine the main influencing factors. The best prediction model is SVR model. It provides a basis for the effective formulation of energy policies and the implementation of economic development programs.

1 Introduction

Energy is a material resource in nature that can provide some form of energy for human beings, and it is an indispensable resource for industrial production, economic development, and people's life in every country. With the rapid development of the economy, the demand for energy is expanding, but energy resources are limited. At the same time, energy consumption also has a serious impact on the environment, such as air pollution, greenhouse gas emissions, etc. [2], with the development of "carbon peak" and "carbon neutral" goals, energy consumption has received more and more attention.

Jiang [3] used the gray correlation model to find out the main influencing factors affecting energy consumption in Chongqing, and established the gray dynamic model, BP neural network model and the composed model to forecast energy consumption. Liu [4] established a VAR model to analyze the relationship between energy consumption and GDP, energy intensity and urbanization level based on the relevant data of Beijing from 1980 to 2010. The authors in [5] proposed two linear models: a transfer function model and a Box-Jenkins model to determine the relationship between energy consumption and a set of control and environmental variables.

Zhao [6] extracted the main factors affecting energy consumption by PCA and then established a regression model to predict energy consumption. Zhang [7] established a VAR model based on the relevant data of Shanxi Province from 1995 to 2012, to analyze the relationship between energy consumption and energy consumption structure, industrial structure and energy price, and five suggestions are put forward to improve the energy consumption situation in Shanxi Province. Based on the statistical data from 1996 to 2021, comprehensive analysis and regression analysis were conducted to determine the main influencing factors. The best prediction model is SVR model. It provides a basis for the effective formulation of energy policies and the implementation of economic development programs.
constructs multiple regression model, time series model and support vector regression model to forecast energy consumption, and uses the mean squared error (MSE), the mean absolute percentage error (MAPE) and the goodness of fit ($R^2$) to evaluate the prediction effect and select the best prediction model. It provides a basis for formulating energy policies and planning economic development programs.

2 Data sources and methodology

The statistical data of 17 indicators and energy consumption data in the impact factor index system of this paper are all from Jiangxi Statistical Yearbook, which are used to screen the impact factors of energy consumption and construct the prediction model.

Pearson correlation coefficient and Spearman correlation coefficient were applied for correlation analysis to screen the factors affecting energy consumption. In view of the time-series characteristics of energy consumption data and the multiplicity of influencing factors, multiple regression model (MLR), time-series model (ARIMA) and support vector regression (SVR) were selected to fit the data and forecast energy consumption.

3 Analysis of impact factors

3.1 Constructing the indicator system

There are many factors affecting energy consumption in Jiangxi Province. By combing and drawing on the influencing factors in the relevant literature, construct a system containing 17 indicators from four aspects: economic, social, technological and energy, as shown in Table 1.

The mainstay of the secondary sector is industry, and the correlation between industrial output and the output value of the secondary sector is close to 1. The correlation between industrial output value and total energy consumption is slightly higher than that of the output value of the secondary sector, as shown in Table 2, so the variable $x_3$ is removed.

After comprehensive analysis, it is determined that 10 indicators are the main influencing factors of total energy consumption.
consumption. They are the regional GDP (x1), the output value of tertiary industry (x4), the industrial output value (x5), the consumption level of residents (x9), the amount of investment in the whole society’s fixed assets (x10), the total number of population (x11), the rate of urbanization (x12), the internal expenditure of the R&D funds (x13), the intensity of energy (x16) and the structure of energy consumption (x17).

① In the economic aspect, economic growth requires the consumption of energy, and the expanding scale of the tertiary sector and the industry-led economic model have a significant effect on the growth of energy consumption. The rising consumption level of the population and the increase in investment lead to the growth of energy consumption while stimulating economic growth. ② In the social aspect, the growth of population size and the increase of urbanization rate lead to the increase of energy consumption. ③ On the technological side, the internal expenditure of R&D funds and energy consumption show two aspects, on the one hand, technological progress promotes social development and improves people's living standards, and good living conditions come at the cost of consuming energy. On the other hand, technological progress improves the efficiency of energy utilization and reduces energy consumption. It is manifested in the increase of internal expenditure on R&D, the growth of energy consumption and the decrease of energy consumption per unit of GDP. ④ In terms of energy. Energy intensity and energy consumption structure have a significant impact on energy consumption, the negative correlation between energy intensity and energy consumption indicates that the energy consumption per unit of GDP is decreasing, and the reduction of the proportion of coal consumption has a positive effect on the total energy consumption.

4 Prediction of total energy consumption

To explore the future development trend of energy consumption in Jiangxi Province, based on the influencing factors confirmed in section 3.2, and combined with relevant data from 1996 to 2021, MLR, ARIMA and SVR models were constructed for prediction. The prediction effects of the three models were compared using MSE, MAPE and R².

4.1 MLR model

The total energy consumption is taken as the dependent variable Y, and the 10 influencing factors are taken as the explanatory variables, and the correlation coefficient matrix shows that the correlation coefficients between the variables are large, and there is a strong correlation between the variables. In order to overcome the existence of multi-collinearity between the variables, stepwise regression is used to select the variables with significant effects for modeling[12].

At the significance level of $\alpha_{entry} = 0.15$, the optimal regression subset is obtained, which contains five variables: GDP (X1), urbanization rate (X12), internal expenditure on R&D funding (X13), and energy consumption structure (X17). The corresponding equation of the model is:

$$y = -9.03e^{-12} + 0.648x_1 + 0.681x_2 - 0.271x_3 + 0.084x_4$$

The t-statistics of the coefficients of X1, X12, X13 and X17 in the equation are all greater than 2, and the p-values are all less than 0.05 (see Figure 1), which passes the test of significance, indicating that the effect of each of the independent variables on Y is significant.

The F-statistic of equation is 3372.64 and p value is less than 0.005, the regression equation passes the test of significance indicating that it is significant. The goodness of fit of the equation $R^2 = 0.9988$, adjusted $R^2 = 0.9985$, indicates that the regression equation as a whole is well fitted.

$$\alpha_{removal} = 0.15$$

$DW = 1.96$, indicating that there is no autocorrelation in the equation. The residual plot shows that there is no heteroskedasticity (see figure 1).

After testing and analyzing, the multiple regression model is valid and can be used for the prediction of total energy consumption.

4.2 ARIMA model

The total energy consumption of Jiangxi Province from 1996 to 2021 was used as sample data for a random time series model, and Eviews was used for modeling. The time series, autocorrelation, and partial autocorrelation were used to determine that the sequence was non-stationary (see figure 2). The p-values of the 6th and 12th order tests in the white noise test were far less than 0.05, indicating that the sequence was a non pure random sequence.
Combining the first-order difference autocorrelation and partial autocorrelation plots and the BIC criterion, the model was determined to be ARIMA(1,1,1). The equation of the model is:

$$Y_t = 0.97Y_{t-1} + e_t - 0.5063e_{t-1}$$  \((2)\)

According to the test result (as shown in Figure 3), the p-values of the coefficients AR(1), ma(1) in the equation and the variance of the model estimation Sigma2 converge to 0, which is less than the significance level (0.05) and passes the test.

The Q-stat= 0.32, prob=0.57, indicating that there is no autocorrelation in the residuals. The JB-stat= 1.06, prob=0.59, indicating that the residuals are consistent with the assumption of normality. The H-stat=0.58, prob=0.46, indicating that the residuals are not heteroskedasticity.

After verification and analysis, the ARIMA model is effective and can be used for predicting the total energy consumption.

**Figure 3.** ARIMA model results
4.3 SVR model

Based on the Python Sklearn package, the SVR model was trained and tested[13]. The standardized data was randomly divided into a training set and a testing set in an 8:2 ratio. Three types of kernel functions (linear kernel function, polynomial kernel function, and radial basis kernel function) were used for training. After parameter tuning, the model performed best when the penalty parameter C was set to 100 and the distance threshold epsilon was set to 0.001. Table 3 shows that the SVR with “Rbf” kernel has the best performance. Therefore, it is determined to establish an SVR prediction model with radial basis function kernel.

4.4 Comparison of 3 forecasting models

Compare the actual and predicted values of three methods (see Figure 4), SVR has the best effect, goodness of fit R² also indicates this point. The MSE and MAPE of the three models shows that: the SVR model is superior to the ARIMA model and the ARIMA model is superior to the MLR model, as shown in Table 4. Through the comprehensive evaluation of fitting accuracy and prediction effect, SVR model has the best performance, and SVR model is selected as the final prediction model.

5 Conclusions and suggestions

5.1 Conclusion

This paper constructs an index system of energy consumption influencing factors that includes 17 indicators from four aspects: economic, social, technological, and energy. Based on comprehensive analysis of statistical data from 1996 to 2021, 10 main factors are determined, and three prediction models are constructed: multiple regression model (MLR), time series model (ARIMA), and support vector regression (SVR). The following conclusion is drawn:

(1) Energy consumption is mainly affected by 10 factors, including GDP, output value of tertiary industry, industrial output value, consumption level of residents, fixed assets investment of the whole society, total population, urbanization rate, internal expenditure of R&D funds, energy intensity, and energy consumption structure.

(2) MLR, ARIMA, and SVR models can all be used for energy consumption prediction in Jiangxi Province, among which SVR has the best prediction effect.

5.2 Suggestions

(1) Promote intensive economic growth and improve the quality of economic development.

Economic growth needs energy support, and the increase in energy consumption brings vitality to the economy, both increasing and decreasing. The GDP of Jiangxi Province is increasing year by year and the economic situation is good, but many of them are extensive industries with high input and high production. Therefore, changing high energy consumption production and consumption patterns in the past and promoting intensive production methods with low energy consumption, low input, and high income are beneficial for economic growth and energy consumption reduction.

(2) Increase investment in technological innovation and reduce industrial energy consumption.
Increase investment in technological innovation, take the path of innovative development, improve energy utilization efficiency, carry out industrial reforms, and reduce the energy consumption of GDP. To increase efforts to develop some high-tech, high-efficiency and environmentally friendly, and low energy consuming industries, optimize industrial structure and resource allocation reasonably, gradually reduce energy consumption in the industrial sector, and achieve industrial transformation.

(3) Raise the entry threshold for investment, prohibit investment in energy-intensive production projects that lack energy and environmental support conditions, and allocate more investment to promote green technology progress. Increase investment in high-end manufacturing, energy-saving and environmental protection industries, and infrastructure green.

(4) Optimize energy consumption structure and improve energy utilization efficiency.

Improve the energy supply system, increase the supply of natural gas and raise the proportion of oil and gas energy consumption. Deepen the exploration of solar and wind energy resources, further develop clean energy sources such as hydropower and geothermal, and reduce reliance on traditional energy. Introduce advanced energy production and consumption technologies to improve energy conversion rates.
